# Chapter 5 <br> CENTRIC TENSION OR COMPRESSION ( AXIAL LOADING ) 

### 5.1 DEFINITION

A construction member is subjected to centric (axial) tension or compression if in any cross section the single distinct stress is the axial force $N$.

If the axial force N is positive we discuss about centric tension (Fig.5.1), respectively if it is negative we have centric compression:

Fig.5.1
Example of a bar subjected only to axial loading:

### 5.2 GEOMETRICAL ASPECT

We study this aspect on a rubber model, with a rectangular cross section (Fig.5.2). On the lateral surface, parallel and equidistant lines are traced.

The model is subjected to centric tension by two equal forces $F$ at each end, the bar reaching a deformed elongated shape.

Fig.5.2
After deformation we observe:

- the initial straight lines remain straight and parallel, respectively perpendicular, to the longitudinal axis of the model.
- the longitudinal lines become longer, all being increased with the same quantity.
- the transversal lines remain parallel and become shorter with the same quantitie.

From these observations we may say that the initial cross sections, plane and parallel on longitudinal axis $G x$ before deformation remain perpendicular and plane after deformation (Bernoulli's hypothesis is valid). So the lengthening is produced by the relative displacement of the cross sections. The lengthening along the longitudinal fibers is uniformly distributed on cross section and the specific elongations $\varepsilon_{\mathrm{x}}$ are also uniformly distributed on cross section:

$$
\varepsilon_{\mathrm{x}}=\text { const. }=\frac{\Delta \mathrm{l}}{\mathrm{l}}
$$

The same observation can be made for the other two specific strains:

$$
\varepsilon_{\mathrm{y}}=\frac{\Delta \mathrm{b}}{\mathrm{~b}}=-\mu \varepsilon_{\mathrm{x}} ; \quad \varepsilon_{\mathrm{z}}=\frac{\Delta \mathrm{h}}{\mathrm{~h}}=-\mu \varepsilon_{\mathrm{x}}
$$

$\mu$ : Poisson's ratio: $\mu=0 \ldots . .0,3$ (ex.: for steel $\mu=0,3$ )
As in practice $\varepsilon_{\mathrm{x}}$ is very small, we may neglect $\varepsilon_{\mathrm{y}}$ and $\varepsilon_{\mathrm{z}}$, the single important specific strain remaining $\varepsilon_{\mathrm{x}}$.

If we observe a rectangle from model, we can see that after deformation the initial straight angles remain also straight, so the specific sliding is null on all directions:

$$
\gamma_{x y}=\gamma_{x z}=\gamma_{y z}=0
$$

In conclusion, the single strain different from zero is the specific elongation $\boldsymbol{\varepsilon}_{\boldsymbol{x}}$ which is constant on cross section.

### 5.3 PHYSICAL ASPECT

Considering the case of a linear-elastic material, we may write Hooke's law:

$$
\sigma=\mathrm{E} \cdot \varepsilon \quad \text { and } \quad \tau=\mathrm{G} \cdot \gamma
$$

For our solicitation these relations become:

$$
\begin{aligned}
& \sigma_{\mathrm{x}}=\mathrm{E} \cdot \varepsilon_{\mathrm{x}}=\text { const. } \\
& \sigma_{\mathrm{y}}=\sigma_{\mathrm{z}}=0 ; \tau_{\mathrm{xy}}=\tau_{\mathrm{xz}}=\tau_{\mathrm{yz}}=0
\end{aligned}
$$

## !!!!! The normal stress $\sigma_{x}$, for the axial solicitation (loading), is always constant

 on cross section (Fig.5.3).

Fig.5.3

### 5.4 THE STATIC ASPECT

For our model, the single stress in cross section is the axial force:

$$
\mathrm{N}=\mathrm{F} \text { (written from exterior })
$$

Writing from interior, the axial force is (3.6):

$$
\begin{gather*}
\mathrm{N}=\int_{\mathrm{A}} \sigma_{x} d A=\sigma_{\mathrm{x}} \int_{\mathrm{A}} d A=\sigma_{\mathrm{x}} \cdot \mathrm{~A} \\
\sigma_{\mathrm{x}}=\frac{\mathrm{N}}{\mathrm{~A}} \tag{5.1}
\end{gather*}
$$

Relation (5.1) represents the formula of the normal stress $\sigma_{x}$ due only to the axial force N , so from axial loading.

From Hook's law, the specific strain:

$$
\varepsilon_{x}=\frac{\sigma_{x}}{E} \text {, or replacing } \sigma_{x} \Rightarrow \varepsilon_{x}=\frac{N}{E \cdot A}
$$

From the geometrical aspect explained in chapter 2, the elongation of a differential element $d x$ is:

$$
\begin{aligned}
& \varepsilon_{\mathrm{x}}=\frac{\Delta \mathrm{dx}}{\mathrm{dx}} \quad(\text { par. 2.1.2) } \\
& \Rightarrow \Delta \mathrm{dx}=\varepsilon_{\mathrm{x}} \cdot \mathrm{dx}=\frac{\mathrm{N}}{\mathrm{E} \cdot \mathrm{~A}} \mathrm{dx}
\end{aligned}
$$

The total elongation of a bar of length $l$, is:

$$
\Delta \mathrm{l}=\int_{0}^{1} \frac{\mathrm{~N}}{\mathrm{E} \cdot \mathrm{~A}} \mathrm{dx}
$$

If $N, E$ and $A$ are constant on the entire length $l$, the total elongation will be:

$$
\begin{equation*}
\Delta \mathrm{l}=\frac{\mathrm{Nl}}{\mathrm{E} \cdot \mathrm{~A}} \tag{5.2}
\end{equation*}
$$

Otherwise: $\quad \Delta \mathrm{l}=\sum \frac{N_{i} \cdot l_{i}}{E_{i} \cdot A_{i}}$
The factor (EA) is called modulus of rigidity at centric tension or compression The main problems regarding the strength calculation are:
a) The strength verification (checking):

$$
\begin{equation*}
\sigma_{\mathrm{x} \text { max }}=\frac{\mathrm{N}_{\max }^{\mathrm{d}}}{\mathrm{~A}_{\text {min }}} \leq \mathrm{R} \text { in Ultimate Limit State } \tag{5.3}
\end{equation*}
$$

where: $\quad N^{d}=n \cdot N^{k}$ : is the design axial force
$\mathrm{N}^{\mathrm{k}}$ : is the characteristic axial force
n : is the partial safety factor for actions
Usually: $\quad R-5 \% \leq \sigma_{x \max } \leq R+3 \%$
Observing the above relations, the maximum normal stress $\sigma_{\mathrm{x} \text { max }}$ will appear in the critical (dangerous) sections, which are:

- sections of maximum axial force : $\mathrm{N}_{\max }$
- sections of minimum (net) area (Fig.5.4): $\mathrm{A}_{\text {min }}=\mathrm{A}_{\text {net }}=\mathrm{A}_{\text {gross }}-\Delta \mathrm{A}$

Fig.5.4
$\mathrm{A}_{\text {net }_{1-1}}=\mathrm{bh}-\mathrm{bd}$
$\mathrm{A}_{\text {net }_{2-2}}=\mathrm{bh}-2 \mathrm{ab}$

- sections of contact between 2 materials of different resistances (Fig.5.5):

Sections $a-a$ and $b-b$ are dangerous sections in the strength computing

Fig.5.5
b) The bar dimensioning

$$
\begin{equation*}
\mathrm{A}_{\mathrm{nec}} \geq \frac{\mathrm{N}_{\text {max }}^{\mathrm{d}}}{\mathrm{R}} \tag{5.4}
\end{equation*}
$$

c) The capable (maximum) axial force (the bearing capacity):

$$
\begin{equation*}
\mathrm{N}_{\text {max }}^{\mathrm{d}} \leq \mathrm{A}_{\text {net }} \mathrm{R} \tag{5.5}
\end{equation*}
$$

### 5.5 CENTRIC TENSION OR COMPRESSION, WHEN WE TAKE INTO ACCOUNT THE EFFECT OF THE MASS FORCES (THE SELFWEIGHT)

Let's assume a cantilever is axially compressed on vertical direction, and the length $l$ is big enough so that its own weight can't be neglected (Fig.5.6).

Fig.5.6
Besides the external force $F$ the bar is subjected by the self-weight $g$, which is a uniformly distributed load along the longitudinal axis of the bar $x$. The normal stress $\sigma_{\mathrm{x}}$ in a section at level $x$ is:

$$
\sigma_{x}=\frac{N(x)}{A}=\frac{F+A \gamma x}{A}=\frac{F}{A}+\gamma \cdot x
$$

The maximum value of $\sigma_{\mathrm{x}}$ is, for $\mathrm{x}=1$ :

$$
\sigma_{x \max }=\frac{F}{A}+\gamma \cdot l=\frac{F+G}{A}
$$

G: the total weight of the bar
The total elongation $\Delta l$ :

$$
\Delta \mathrm{l}=\int_{0}^{1} \frac{\mathrm{~N}(\mathrm{x})}{\mathrm{EA}} \mathrm{dx}=\int_{0}^{1} \frac{\mathrm{~F}+\mathrm{A} \gamma \mathrm{x}}{E A} \mathrm{dx}=\frac{\mathrm{Fl}}{E A}+\frac{A \gamma}{E A} \frac{\mathrm{x}^{2}}{2} l_{0}^{l}=\frac{\mathrm{Fl}}{E A}+\frac{1}{2} \frac{\mathrm{Gl}}{E A}
$$

Relation of $\Delta l$ may be written shorter, for bars with different $\mathrm{N}, \mathrm{E}$ and A :

$$
\Delta l=\sum \Delta l_{\mathrm{i}}=\sum\left(\frac{N_{\mathrm{i}} \mathrm{l}_{\mathrm{i}}}{\mathrm{E}_{\mathrm{i}} \mathrm{~A}_{\mathrm{i}}}+\frac{1}{2} \frac{\mathrm{G}_{\mathrm{i}} \mathrm{l}_{\mathrm{i}}}{\mathrm{E}_{\mathrm{i}} \mathrm{~A}_{\mathrm{i}}}\right)
$$

We note: $\mathrm{N}_{\mathrm{i}} \mathrm{I}_{\mathrm{i}}+\frac{1}{2} G_{\mathrm{i}} \mathrm{l}_{\mathrm{i}}=\Omega_{\mathrm{Ni}}$ : the area of the characteristic axial force diagram. $\Delta \mathrm{l}$ will be then:

$$
\begin{equation*}
\Delta \mathrm{l}=\sum \frac{\Omega_{\mathrm{Ni}}}{\mathrm{E}_{\mathrm{i}} \mathrm{~A}_{\mathrm{i}}} \tag{5.6}
\end{equation*}
$$

The relation will be written separately for each part of the bar for which $N, E$ and $A$ are constant, the total elongation $\Delta l$ being finally their sum $\sum \Delta l_{i}$.

### 5.6 STRESSES ON AN OBLIQUE PLANE

Let's consider a tensioned bar and a cross section 1-1 which is perpendicular to the longitudinal bar axis (Fig.5.7). Removing one part, in the cross section 1-1 of the other part the effect of the removed part is introduced by distributed internal forces measured by unit stresses $\sigma_{x}$.

## Fig.5.7

In section 1-1 the resultant of the internal forces is the axial force:

$$
N=\sigma_{x} \cdot A
$$

Now we consider another section 2-2, which will be inclined with an angle $\alpha$ with respect to section 1-1 (Fig.5.8).

Fig.5.8
Similarly, removing one part of the bar, the other part will be in equilibrium if in the inclined section $2-2$ it is introduced the effect of the removed part also by internal distributed forces.

These two sections 1-1 (transversal) and 2-2 (oblique) are fictitious sections and they can't modify the state of stresses from bar, meaning the axial force and the direction of the internal forces ( $\sigma_{\mathrm{x}}$ respectively $\mathrm{p}_{\mathrm{n}}$ ). Therefore through the cross section 1-1 the same axial force will be transmitted as through the inclined section 2-2, and the unit stresses $\sigma_{\mathrm{x}}$ and $p_{\mathrm{n}}$ will be uniformly distributed on both sections. We may write then:

$$
\mathrm{N}=\sigma_{\mathrm{x}} \cdot \mathrm{~A}=\mathrm{p}_{\mathrm{n}} \cdot \mathrm{~A}_{\mathrm{n}}
$$

But: $\cos \alpha=\frac{\mathrm{A}}{\mathrm{A}_{\mathrm{n}}} \Rightarrow \mathrm{A}_{\mathrm{n}}=\frac{\mathrm{A}}{\cos \alpha}$
Replacing: $\quad \sigma_{\mathrm{x}} \cdot \mathrm{A}=\mathrm{p}_{\mathrm{n}} \cdot \frac{\mathrm{A}}{\cos \alpha}=>\mathrm{p}_{\mathrm{n}}=\sigma_{\mathrm{x}} \cdot \cos \alpha$
Decomposing $\mathrm{p}_{\mathrm{n}}$ (Fig.5.9), we obtain the normal, respective tangential component of the unit stress $p_{n}$ in the inclined section:

$$
\begin{aligned}
& \sigma_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}} \cdot \cos \alpha=\sigma_{\mathrm{x}} \cdot \cos ^{2} \alpha=\frac{\sigma_{\mathrm{x}}}{2}(1+\cos 2 \alpha) \\
& \tau_{\mathrm{ns}}=-\mathrm{p}_{\mathrm{n}} \cdot \sin \alpha=-\sigma_{\mathrm{x}} \cdot \sin \alpha \cdot \cos \alpha=-\frac{\sigma_{\mathrm{x}}}{2} \cdot \sin 2 \alpha
\end{aligned}
$$

Fig.5.9
The sign (-) from the shear stress $\tau_{\text {ns }}$ appear from a reason of positive conventional orientation of the tangential stress $\tau$ in the system of axis $n-s$ from section 2-2.

For different values of the angle $\alpha$, different stresses $\sigma_{\mathrm{n}}$ and $\tau_{\mathrm{ns}}$ are obtained. We are interested in the extreme values of $\sigma_{\mathrm{n}}$ and $\tau_{\mathrm{ns}}$ which are obtained for the trigonometrically values $\cos 2 \alpha= \pm 1$ and $\sin 2 \alpha= \pm 1$ :

$$
\begin{aligned}
& \cos 2 \alpha=1 \Rightarrow \alpha=0=>A_{n}=A=>\left\{\begin{array}{c}
\sigma_{\mathrm{n}}=\sigma_{\mathrm{x}}=\sigma_{\mathrm{max}} \\
\tau_{\mathrm{ns}}=0
\end{array}\right. \\
& \cos 2 \alpha=-1 \Rightarrow \alpha=\frac{\pi}{2}=90^{\circ} \Rightarrow \mathrm{A}_{\mathrm{n}}=\mathrm{A}_{\mathrm{z}}=>\left\{\begin{array}{c}
\sigma_{\mathrm{n}}=\sigma_{\mathrm{z}}=0 \\
\tau_{\mathrm{ns}}=0
\end{array}\right. \\
& \sin 2 \alpha=1 \Rightarrow \alpha=\frac{\pi}{4}=45^{\circ}=>\mathrm{A}_{\mathrm{n}}=\mathrm{A}_{\mathrm{n}_{45}}=>\left\{\begin{array}{c}
\sigma_{\mathrm{n}}=\frac{\sigma_{\mathrm{x}}}{2} \\
\tau_{\mathrm{ns}}=-\frac{\sigma_{\mathrm{x}}}{2}=\tau_{\mathrm{min}}
\end{array}\right. \\
& \sin 2 \alpha=-1 \Rightarrow \alpha=\frac{3 \pi}{4}=135^{\circ}\left(-45^{\circ}\right)=>\mathrm{A}_{\mathrm{n}}=\mathrm{A}_{\mathrm{n}_{135}}=>\left\{\begin{array}{c}
\sigma_{\mathrm{n}}=\frac{\sigma_{\mathrm{x}}}{2} \\
\tau_{\mathrm{ns}}=\frac{\sigma_{\mathrm{x}}}{2}=\tau_{\max }
\end{array}\right.
\end{aligned}
$$

In conclusion, the maximum normal stresses $\sigma_{\mathrm{x} \text { max }}$ appear in the cross section, while the extreme shear stresses $\tau_{\text {max,min }}$ appear in the sections inclined with $45^{\circ}$.

To have a view of the state of stresses around an interior point K from bar, these results can be represented in a plan, called the plan of the unit stresses (Fig.5.10).

Fig.5.10

### 5.7 UNDETERMINED STATIC STRUCTURES (HYPERSTATIC SYSTEMS) SUBJECTED TO AXIAL SOLICITATION

Structures for which internal forces and reactions cannot be determined from statics alone are said to be statically indeterminate.

A structure will be statically indeterminate whenever it is held by more supports than are required to maintain its equilibrium.

In these structures, we have more unknowns than equations, that's why we introduce other relationships written in deformations in order to find the state of stresses from structure.

### 5.7.1 Double fixed bar actioned by a concentrate force

Let's draw the diagram of the axial force for a double fixed bar (Fig.5.11), having a constant rigidity EA.

In the fixed support the vertical reactions are introduced, $\mathrm{R}_{\mathrm{VA}}$ and $\mathrm{R}_{\mathrm{VB}}$, reactions which assure the static equilibrium:

$$
R_{V A}+R_{V B}=P
$$

To obtain the reaction $R_{V A}$ and $R_{V B}$ we have to write a supplementary condition in deformations, writing the total elongation of the bar $\Delta \mathrm{l}=0$ :

$$
\Delta l=\Delta l_{A-C}+\Delta l_{C-B}=\frac{R_{V A} \cdot b}{E A}+\frac{\left(R_{V A}-P\right) a}{E A}=0 \Rightarrow \quad R_{V A}=\mathrm{P} \frac{\mathrm{a}}{\mathrm{l}} \text { and } R_{V B}=\mathrm{P} \frac{\mathrm{~b}}{\mathrm{l}}
$$

Fig.5.11

### 5.7.2 Undetermined system of parallel bars.

We consider a very rigid bar (bar of infinite rigidity), suspended horizontally by 3 tyrants (tie rods) made from different materials and with different areas ( $\mathrm{E}_{1} \mathrm{~A}_{1}$, $\mathrm{E}_{2} \mathrm{~A}_{2}, \mathrm{E}_{3} \mathrm{~A}_{3}$ ), so with different rigidities (Fig.5.12). The rigid bar ABCDE is hinged in A , and solicitated by a concentrate force P in E .

Fig.5.12

Let's compute the axial stresses $\mathrm{N}_{\mathrm{i}}$ from rods. First, an equation of moment about the hinged support is written:
(a) $(\boldsymbol{\Sigma} \mathrm{M})_{\mathrm{A}}=0: \mathrm{N}_{1} \cdot \mathrm{a}+\mathrm{N}_{2} \cdot \mathrm{~b}+\mathrm{N}_{3} \cdot \mathrm{c}=\mathrm{P} \cdot \mathrm{d}$

Equations in deformations are written considering that the rigid bar remains rectilinear after the system deformation:
(b) $\frac{\Delta l_{3}}{\Delta l_{1}}=\frac{c}{a}$

$$
\frac{\Delta l_{2}}{\Delta l_{1}}=\frac{b}{a}
$$

$$
\frac{\Delta l_{3}}{\Delta l_{2}}=\frac{c}{b}
$$

But: $\quad \Delta l_{1}=\frac{N_{1} \mathrm{l}}{\mathrm{E}_{1} \mathrm{~A}_{1}} \quad \Delta \mathrm{l}_{2}=\frac{\mathrm{N}_{2} \mathrm{l}}{\mathrm{E}_{2} \mathrm{~A}_{2}}$
(b) $\frac{\mathrm{N}_{3} \mathrm{a}}{\mathrm{E}_{3} \mathrm{~A}_{3}}=\frac{\mathrm{N}_{1} \mathrm{c}}{\mathrm{E}_{1} \mathrm{~A}_{1}} \quad \frac{N_{2} \mathrm{a}}{\mathrm{E}_{2} \mathrm{~A}_{2}}=\frac{\mathrm{N}_{1} \mathrm{~b}}{\mathrm{E}_{1} \mathrm{~A}_{1}}$
$\Rightarrow \quad N_{3}=N_{1} \frac{c}{a} \frac{E_{3} A_{3}}{E_{1} A_{1}}$ and $N_{2}=N_{1} \frac{b}{a} \frac{E_{2} A_{2}}{E_{1} A_{1}}$
(a) $N_{1} a+N_{1} \frac{b^{2}}{a} \frac{E_{2} A_{2}}{E_{1} A_{1}}+N_{1} \frac{c^{2}}{a} \frac{E_{3} A_{3}}{E_{1} A_{1}}=P d$
$\mathrm{N}_{1}\left(\mathrm{a}^{2} \mathrm{E}_{1} \mathrm{~A}_{1}+\mathrm{b}^{2} \mathrm{E}_{2} \mathrm{~A}_{2}+\mathrm{c}^{2} \mathrm{E}_{3} \mathrm{~A}_{3}\right)=\operatorname{PdaE}_{1} \mathrm{~A}_{1}$
If: $\quad a^{2} E_{1} A_{1}+b^{2} E_{2} A_{2}+c^{2} E_{3} A_{3}=\lambda$

$$
\Rightarrow \quad N_{1}=P d \frac{a}{\lambda} E_{1} A_{1} ; \quad N_{2}=\operatorname{Pd} \frac{b}{\lambda} E_{2} A_{2} ; \quad N_{3}=\operatorname{Pd} \frac{\mathrm{c}}{\lambda} E_{3} A_{3}
$$

From equations of vertical and horizontal equilibrium we may calculate also the reactions from A .

### 5.7.3. Undetermined system of concurrent bars.

Three concurrent tie rods are subjected to tension by the concentrate force P (Fig.5.13). The inclined rods are identically (the same length and rigidity $\mathrm{E}_{1} \mathrm{~A}_{1}$ ), while the vertical bar has the rigidity $\mathrm{E}_{2} \mathrm{~A}_{2}$. Let's calculate the stresses from rods.

Isolating node 0 we have:

Fig.5.13

The horizontal equilibrium is an identity from symmetry reason (from geometrical and rigidity point of view), also the moment equilibrium is an identity (all forces pass through point O ). The single equation which can be written is the vertical equilibrium equation:

$$
\begin{equation*}
2 \mathrm{~N}_{1} \cos \alpha+\mathrm{N}_{2}=\mathrm{P} \tag{a}
\end{equation*}
$$

After deformation the new angle $\alpha \cong \alpha$, as the lengthening $\Delta l_{1}$ and $\Delta l_{2}$ are very small. We may write a second equation in deformations:

$$
\begin{equation*}
\Delta \mathrm{l}_{1}=\Delta \mathrm{l}_{2} \cos \alpha \tag{b}
\end{equation*}
$$

or: $\frac{\mathrm{N}_{1} \mathrm{l}_{1}}{\mathrm{E}_{1} \mathrm{~A}_{1}}=\frac{\mathrm{N}_{2} \mathrm{l}_{2}}{\mathrm{E}_{2} \mathrm{~A}_{2}} \cos \alpha$
but: $\quad 1_{2}=1=1_{1} \cos \alpha$
$\Rightarrow \quad \frac{\mathrm{N}_{1} \mathrm{I}_{1}}{\mathrm{E}_{1} \mathrm{~A}_{1}}=\frac{\mathrm{N}_{2} \mathrm{l}_{1} \cos \alpha}{\mathrm{E}_{2} \mathrm{~A}_{2}} \cos \alpha \quad \Rightarrow \quad \mathrm{~N}_{1}=\mathrm{N}_{2} \frac{\mathrm{E}_{1} \mathrm{~A}_{1}}{\mathrm{E}_{2} \mathrm{~A}_{2}} \cos ^{2} \alpha$
From (a): $\quad 2 \mathrm{~N}_{2} \frac{\mathrm{E}_{1} \mathrm{~A}_{1}}{\mathrm{E}_{2} \mathrm{~A}_{2}} \cos ^{3} \alpha+\mathrm{N}_{2}=\mathrm{P}$

$$
N_{2}=\frac{P}{\frac{2 E_{1} A_{1}}{E_{2} A_{2}} \cos ^{3} \alpha+1} \quad N_{2}=\frac{P}{\frac{2 E_{1} A_{1}}{E_{2} A_{2}} \cos ^{3} \alpha+1} \frac{E_{1} A_{1}}{E_{2} A_{2}} \cos ^{2} \alpha
$$

### 5.7.4 The effect of the temperature variation in undetermined systems.

Fig.5.14

From vertical equilibrium equation:

$$
\begin{equation*}
2 \mathrm{~N}_{1} \cos \alpha+\mathrm{N}_{2}=0 \tag{a}
\end{equation*}
$$

The condition in displacements will be written also:

$$
\begin{equation*}
\Delta \mathrm{l}_{1}=\Delta \mathrm{l}_{2} \cos \alpha \tag{b}
\end{equation*}
$$

But in the expression of $\Delta 1$ we must add a term that takes into account the temperature variation:

$$
\Delta \mathrm{l}_{\mathrm{t}}=\alpha 1 \Delta \mathrm{t} \quad \alpha \text { : thermal expansion coefficient }\left(1 /{ }^{\circ} \mathrm{C}\right)
$$

Equation (b) will be then:

$$
\begin{equation*}
\frac{N_{1} l_{1}}{E A}+\alpha l_{1} \Delta t=\left(\frac{N_{2} l_{2}}{E A}+\alpha l_{2} \Delta t\right) \cos \alpha \tag{b'}
\end{equation*}
$$

With $1_{2}=1_{1} \cos \alpha=>$
$\frac{\mathrm{N}_{1}}{\mathrm{EA}}+\alpha \Delta \mathrm{t}=\left(\frac{\mathrm{N}_{2}}{\mathrm{EA}}+\alpha \Delta \mathrm{t}\right) \cos ^{2} \alpha$
$\frac{1}{E A}\left(N_{1}-N_{2} \cos ^{2} \alpha\right)=\alpha \Delta t\left(\cos ^{2} \alpha-1\right)$
From (a): $N_{2}=-2 N_{1} \cos \alpha$ which introduced in (b") give the stresses:

$$
\begin{aligned}
& N_{1}=E A \cdot \alpha \Delta t \frac{\cos ^{2} \alpha-1}{1+2 \cos ^{3} \alpha} \\
& N_{2}=-2 E A \cdot \alpha \Delta t \frac{\cos \alpha\left(\cos ^{2} \alpha-1\right)}{1+2 \cos ^{3} \alpha}
\end{aligned}
$$

### 5.7.5 Bars with unhomogene sections, subjected to centric tension or compression

In all previous examples of undetermined structures, we admitted that section is homogene and the unit stresses $\sigma$ have uniform distribution on section. In practice there are also bars with unhomogene cross sections, as: columns from reinforced concrete, rods from copper or aluminum with steel core, etc.

If we admit that the axial force N which acts in a section of such bar is known, let's determine the repartition of the normal stresses $\sigma$ in that section (Fig.5.15).

Both materials from rod will overtake a fraction from the axial force $\mathrm{N}=\mathrm{F}$, the copper: $\mathrm{N}_{\mathrm{cu}}$, the steel: $\mathrm{N}_{\mathrm{ol}}$.

Fig.5.15

## Obviously:

$$
\begin{equation*}
\mathrm{N}_{\mathrm{cu}}+\mathrm{N}_{\mathrm{ol}}=\mathrm{N} \tag{a}
\end{equation*}
$$

We need also a condition written in deformations. We admit that the materials are solidarized between them, so their deformations must be equal. We write this condition in specific deformations $\varepsilon$, from Hook's law $(\sigma=\mathrm{E} \varepsilon)$ :

$$
\begin{equation*}
\varepsilon=\frac{\sigma_{\mathrm{ol}}}{\mathrm{E}_{\mathrm{ol}}}=\frac{\sigma_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{cu}}} \tag{b}
\end{equation*}
$$

We multiply each fraction with the correspondent area $A_{i}$ and writing that these fractions are equal to the sum of numerators divided to the sum of denominators, we obtain:

$$
\begin{gathered}
\frac{\sigma_{o l}}{\mathrm{E}_{\mathrm{ol}}}=\frac{\sigma_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{cu}}}=\frac{\sigma_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}}=\frac{\sigma_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}}=\frac{\sigma_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\sigma_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}}=\frac{\mathrm{N}_{\mathrm{ol}}+\mathrm{N}_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}}=\frac{N}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}} \\
\Rightarrow \quad \sigma_{\mathrm{cu}}=\frac{\mathrm{E}_{\mathrm{cu}}}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}} \quad \text { and } \quad \mathrm{N}_{\mathrm{cu}}=\sigma_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}} \\
\sigma_{\mathrm{ol}}=\frac{\mathrm{E}_{o l}}{\mathrm{E}_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}+\mathrm{E}_{\mathrm{cu}} \mathrm{~A}_{\mathrm{cu}}} \quad \text { and } \quad \mathrm{N}_{\mathrm{ol}}=\sigma_{\mathrm{ol}} \mathrm{~A}_{\mathrm{ol}}
\end{gathered}
$$

### 5.8 APPLICATIONS

5.8.1 A steel column sits on a concrete foundation by a metal base plate (Fig.5.16). The following information are known: the load parameters are $\mathrm{n}_{\mathrm{F}}=1.5$ and $\mathrm{n}_{\gamma}=1.35$; the design strength of the materials are $\mathrm{R}_{\text {steel }}=2100 \mathrm{daN} / \mathrm{cm}^{2}$, $\mathrm{R}_{\text {concrete }}=55 \mathrm{daN} / \mathrm{cm}^{2}, \mathrm{R}_{\text {soil }}=3.2 \mathrm{daN} / \mathrm{cm}^{2}$; Young modulus of the materials are $\mathrm{E}_{\text {steel }}=2.1 \times 10^{6} \mathrm{daN} / \mathrm{cm}^{2}, \mathrm{E}_{\text {concrete }}=240000 \mathrm{daN} / \mathrm{cm}^{2}$; specific weight of concrete $\gamma_{\text {concrete }}=25 \mathrm{kN} / \mathrm{m}^{3}$. Make the strength check and dimension the steel plate ( $\mathrm{l}=$ ?). Then compute the total shortening $\Delta \mathrm{l}$.

Fig.5.16

The characteristic weight of the foundation is: $G_{f}^{k}=75 \mathrm{kN}$
The design weight of the foundation is: $G_{f}^{d}=75 \cdot 1.35=101.25 \mathrm{kN}$ The axial force diagram (both characteristic and design) is presented in fig.5.16.1.
We shall make the strength check in section 2-2 and from section 1-1 we shall dimension the steel plate. Both calculations are strength calculations made with the design axial forces $\mathrm{N}^{\mathrm{d}}$

Fig.5.16.1

## Section 1-1:

$$
\sigma_{x}=\frac{N^{d}}{A}=\frac{600 \cdot 10^{2}}{1.5 l^{2}} \leq \mathrm{R}_{\text {concrete }}=55 \mathrm{daN} / \mathrm{cm}^{2} \rightarrow l \geq 26.96 \mathrm{~cm} \rightarrow l=27 \mathrm{~cm}
$$

Section 2-2:

$$
\sigma_{x}=\frac{N^{d}}{A}=\frac{941.25 \cdot 10^{2}}{200 \cdot 150}=3.13 \mathrm{daN} / \mathrm{cm}^{2}<\mathrm{R}_{\text {soil }}=3.2 \mathrm{daN} / \mathrm{cm}^{2}
$$

The total shortening $\Delta l$ is calculated with formula 5.6 and using the characteristic axial force $\mathrm{N}^{\mathrm{k}}$ diagram:

$$
\Delta \mathrm{l}=-\left[\frac{400 \cdot 10^{2} \cdot 450}{2.1 \cdot 10^{6} \cdot 77.8}+\frac{(560+635) \cdot 10^{2} \cdot 100}{2 \cdot 240000 \cdot 200 \cdot 150}\right]=-0.1184 \mathrm{~cm}
$$

5.8.2 The bar of infinite rigidity ABC is fixed in points B and C by 2 tie rods of different rigidities (Fig.5.17). Knowing: $a=1.2 \mathrm{~m}, A_{2}=2 A_{1}, A_{1}=A_{0}=5 \mathrm{~cm}^{2}$, calculate:

1. The axial forces $N_{l}$ and $N_{2}$ in the two rods.
2. The load parameter $q$ from the condition that in both rods the maximum normal stress $\sigma_{x \max }=2000 \mathrm{daN} / \mathrm{cm}^{2}$ should not be exceeded
3. If the tie rods areas $A_{1}=A_{2}=A_{0}$ calculate the vertical displacement of point $D\left(\mathrm{E}=2.1 \times 10^{6} \mathrm{daN} / \mathrm{cm}^{2}\right)$

Fig.5.17
1.

Fig.5.18

From the geometry of the structure (Fig.5.17 and 5.18):

$$
\begin{aligned}
& l_{1}=\frac{3 a}{\sin \alpha} \\
& l_{2}=\frac{3 a}{\sin \beta}
\end{aligned}
$$

As the bar ABC has infinite rigidity it can only move (remaining straight), rotating around the hinge from point A (Fig.5.18). After displacement the rigid bar reaches the dotted position from Fig.5.18. Point B is displaced with $\delta_{\mathrm{B}}$, while point C is displaced with $\delta_{\mathrm{C}}$.

In points $B$ and $C$ from Fig.5.18 the axial forces from rods $N_{1}$ and $N_{2}$ are introduced. The moment equilibrium equation is:

$$
\begin{gathered}
\left(\sum M\right)_{A}=0: q \cdot 4 a \cdot 2 a-N_{1} \sin \alpha \cdot 3 a-N_{2} \sin \beta \cdot 4 a=0 \rightarrow \\
3 N_{1} \sin \alpha+4 N_{2} \sin \beta=8 q a
\end{gathered}
$$

From Fig. 5.18 we may write a supplementary condition in deformations:

$$
\begin{equation*}
\frac{\delta_{B}}{\delta_{C}}=\frac{3 a}{4 a} \tag{2}
\end{equation*}
$$

But:
$\delta_{B}=\frac{\Delta l_{1}}{\sin \alpha}$ and $\delta_{C}=\frac{\Delta l_{2}}{\sin \beta}$. With these equation (2) becomes:
$4 \frac{\Delta l_{1}}{\sin \alpha}=3 \frac{\Delta l_{2}}{\sin \beta} \rightarrow 4 \frac{N_{1} l_{1}}{E A_{1} \sin \alpha}=3 \frac{N_{2} l_{2}}{E A_{2} \sin \beta}\left(2^{\prime}\right) \rightarrow N_{1}=\frac{3 N_{2} \sin ^{2} \alpha}{8 \sin ^{2} \beta}$
Replacing $\mathrm{N}_{1}$ in equation (1) we get: $N_{2}=\frac{9,6 q}{\frac{9 \sin ^{3} \alpha}{8 \sin ^{2} \beta}+4 \sin \beta}$
Function the load parameter $q$ the axial forces from rods will be:

$$
\mathrm{N}_{2}=2.739 \mathrm{q} \text { and } \mathrm{N}_{1}=1.426 \mathrm{q}
$$

2. From the condition that $\sigma_{x \max }=2000 \mathrm{daN} / \mathrm{cm}^{2}$ in both rods:

$$
\begin{aligned}
& \sigma_{x_{1}}=\frac{1.426 \mathrm{q} \cdot 10^{2}}{5} \leq 2000 \rightarrow q \leq 70.12 \mathrm{kN} / \mathrm{m} \\
& \sigma_{x_{2}}=\frac{2.739 \mathrm{q} \cdot 10^{2}}{10} \leq 2000 \rightarrow q \leq 73.02 \mathrm{kN} / \mathrm{m}
\end{aligned}
$$

The load parameter $q$ is the minimum between the two above values, so:

$$
\mathrm{q}=70.12 \mathrm{kN} / \mathrm{m}
$$

3. If $A_{1}=A_{2}=A_{0}=5 \mathrm{~cm}^{2}$, we must re-calculate the axial forces $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$.

From the previous equation (2) : $4 \frac{N_{1} l_{1}}{E A_{1} \sin \alpha}=3 \frac{N_{2} l_{2}}{E A_{2} \sin \beta} \rightarrow N_{1}=\frac{3 N_{2} \sin ^{2} \alpha}{4 \sin ^{2} \beta}$
Inserting $\mathrm{N}_{1}$ in equation (1) and with the load parameter $\mathrm{q}=70.12 \mathrm{kN} / \mathrm{m}$, the axial forces from rods will be:

$$
\mathrm{N}_{2}=62.47 \mathrm{kN} \quad \text { and } \quad \mathrm{N}_{1}=65.07 \mathrm{kN}
$$

From Fig.5.18 we may write:

$$
\frac{\delta_{B}}{\delta_{D}}=\frac{3 a}{1.5 a} \rightarrow \quad \delta_{D}=\frac{\delta_{B}}{2}=\frac{N_{1} \frac{3 a}{\sin \alpha}}{2 E A_{0} \sin \alpha}=0.223 \mathrm{~cm}
$$
